Abstract: Family planning is widely acknowledged as an important intervention towards achieving Sustainable Development Goals (SDGs) three (4) and five (5) as it has proven to reduce maternal and child mortality. Family planning can prevent unwanted pregnancies and unsafe abortions. The aim of this study was to determine various factors that influence the uptake of modern family planning among women of reproductive age in South-eastern Nigeria. The study used data obtained from Nigeria Demographic and Health Survey (NDHS) 2013. Factors considered were drawn from the dataset. Analysis was carried out using Stata version 12.1. Multivariate logistic regression analysis was used to determine relationship between various factors and use of modern family planning methods. Level of significance was set at 0.05. The total number of participants in the study was 2,816. Twelve point fifty seven percent (12.57%) of the participants were currently using modern family planning methods. The highest proportion of use was 25.57% in Ebonyi State, while the lowest was 16.94% in Imo State. The only identified predictor of use of modern family planning use was educational status. The women who had at least secondary education were almost twice (1.82 times) more likely to use modern family planning methods than those who had only primary education or less (OR=1.82, 95% CI: 1.4-2.4, P<0.001). Measures should be taken to increase female literacy, as this will most likely lead to improved uptake of modern family planning among the respondents.

Keywords: Modern family planning, South-eastern Nigerian women.

INTRODUCTION

Family planning is widely acknowledged as an important intervention towards achieving Sustainable Development Goals (SDGs) three (4) and five (5) as it has proven to reduce maternal and child mortality. Family planning can prevent unwanted pregnancies and unsafe abortions. Some family planning methods such as condom usage can protect individuals from Sexually Transmitted Infections (STIs) including HIV/AIDS [1,2]. Family planning has also been found to promote gender equality as well as promote educational and economic empowerment for women [2]. Despite the enormous benefits of family planning services, the uptake of the service still remains low in Sub-Saharan Africa [3]. This has resulted to high rates of unwanted pregnancies, unplanned deliveries, unsafe abortions and maternal mortalities in Sub-Saharan Africa [4].

According to the World Health Organisation (WHO)[5], promotion of family planning and ensuring access to preferred contraceptive methods for women and couples is essential to securing the well-being and autonomy of women, while supporting the health and development of communities.

WHO states that benefits of family planning include[5]: I. Preventing pregnancy-related health risks in women: A woman’s ability to choose if and when to become pregnant has a direct impact on her health and well-being. Family planning allows spacing of pregnancies and can delay pregnancies in young women
Family planning reduces the risk of unintended pregnancies among women living with HIV, resulting in fewer infected babies and orphans. In addition, male and female condoms provide dual protection against unintended pregnancies and against STIs including HIV; IV. Empowering people and enhancing education: Family planning enables people to make informed choices about their sexual and reproductive health. Family planning represents an opportunity for women to pursue additional education and participate in public life, including paid employment in non-family organizations. Additionally, having smaller families allows parents to invest more in each child. Children with fewer siblings tend to stay in school longer than those with many siblings; V. reducing adolescent pregnancies: Pregnant adolescents are more likely to have preterm or low birth-weight babies. Babies born to adolescents have higher rates of neonatal mortality. Many adolescent girls who become pregnant have to leave school. This has long-term implications for them as individuals, their families and communities; V. slowing population growth: Family planning is key to slowing unsustainable population growth and the resulting negative impacts on the economy, environment, and national and regional development efforts.

It is important that family planning is widely available and easily accessible through midwives and other trained health workers to anyone who is sexually active. Midwives are trained to provide (where authorised) locally available and culturally acceptable contraceptive methods. Other trained health workers, for example community health workers, also provide counselling and some family planning methods, for example pills and condoms. For methods such as sterilization, women and men need to be referred to a clinician.

The 2013 Nigeria Demographic and Health Survey reported that 85 percent of women and 95 percent of men knew about a contraceptive method [6]. Overall, 15 percent of currently married women in Nigeria were using a contraceptive method, an increase of only 2 percentage points since the 2003 NDHS [6]. The overall contraceptive prevalence among women in Nigeria was 16 percent [6]. The South West zone had the highest proportion of women currently using a family planning method (38 %), followed by the South East (29%). The lowest proportion of married women using a family planning method was in the North East (3 percent). Among the states, Lagos and Kwara had the highest percentages of women using any method (48 percent and 40 percent, respectively).

Although the South East had the second highest proportion of women using contraceptives, it is good to disaggregate the data and look at the different states and some determinants of use of modern family planning methods. This study aimed at narrowing into the South Eastern region of Nigeria using data generated by the 2013 Nigeria Demographic and Health Study (NDHS) and explores some possible determinants of use of modern family planning methods.

**METHODOLOGY**

The Demographic and Health Surveys (DHSs) are nationally-representative household surveys that provide data for a wide range of monitoring and impact evaluation indicators in the areas of population, health, and nutrition for low and middle income countries [7]. This study used Nigeria Demographic and Health Survey 2013 dataset. Ethical approval was obtained from the ethical committee of Chukwuemeka Odumegwu Ojukwu University Teaching Hospital, Awka. Only females of reproductive age (15 to 49 years) from the South-eastern geo-political zone of the country were included in the study. The women were two thousand eight hundred and sixteen (2,816) in number. Data was analysed using Stata data analysis software Version 12.1.

Some basic characteristics of the women were explored including: the state they belong to, the age of the women, the highest educational level they attained, their place of residence (urban/rural), current method of family planning, current marital status. Frequencies and percentages were displayed in tables. Binomial logistic regression was used to establish the correlates of use of modern family planning among the women. The dependent variable was the current family planning method of the women. This variable was originally grouped into four possible outcomes: No family planning method, traditional method, folkloric method and modern method. But for the purpose of this study, this variable was re-coded into only two possible outcomes: Modern family planning method and others. The independent variables were: educational level, age of the women, place of residence (urban/rural) and marital status of the women. Some of the independent variables which had more than two categories were re-coded into only two categories. The educational level was re-coded into two categories: minimum of
secondary school and primary school or less. Age was re-coded into two categories: 25 years or more and 24 years or less. Marital status was re-coded into two categories: currently married and others. The p-value was set at 0.05 meaning that any p-value that is less than 0.05 was considered statistically significant.

RESULTS

Table 1: Distribution of the respondents according to States in the Southeast geo-political zone of Nigeria

<table>
<thead>
<tr>
<th>State of residence</th>
<th>Frequency</th>
<th>Percentage</th>

<td>100.00</td>
</tr>
</tbody>
</table>

Table 7 shows a cross tabulation of the use of family planning versus the state of the respondents. Abia State has the highest proportion of respondents using modern family planning methods (16.90%). On the other hand, only 6.11% of the respondents in Ebonyi state use modern family planning methods.

secondary education or more were 1.8 times more likely to use modern family planning methods than those who had primary education or less, and this was statistically significant (p<0.001).

DISCUSSION

Looking at the distribution of the respondents according to their states, the most common state was Ebonyi state (25.57%). Imo state was the least represented (16.94%). The most common age group was the 25-29 years age group which made up 28.55% of all the respondents, while the least represented age group was the 15-19 years age group (2.10%). The commonest age group in this study corresponds with the commonest age group among women of reproductive age in all the 6 geo-political zones in the country [8]. On the contrary, the least common age group nationally is the 45-49 years age group unlike 15-19 years in the index study [8]. Similarly, a study in Egypt reported that the commonest age group was the 25-29 years age group [9]. Only 5.53% of the women had no formal education, indicating that majority of the women who participated in this study was educated. This is a clear departure from the results of a nationally representative study which reported that almost half (46.89%) of Nigerian women studied had no formal education [8]. This finding underscores the importance of disaggregation of data. This study demonstrates that the women in the south-eastern part of Nigeria have a far higher level of literacy compared with the national average [8].

Among the women in this study 12.57% were using modern family planning methods. This is higher than the national average of 9.68% as reported in a nationally representative study [8]. Among Northern Nigerian women, only 5.33% use modern family planning methods. The great difference between the South-eastern women and the Northern women may be because of their differences in education. While 94.67% of the South-eastern women had formal education, only 34.1% of the Northern Nigerian women had formal education [10]. A study among Nigerian women had shown that those who had secondary education or more were 2.9 times more likely than those who had primary education or less to use modern family planning methods [8].

In the present study the women who had minimum of secondary education were almost 2 times (1.8 times) more likely than those with only primary education to use modern family planning methods. This agrees with many studies which have demonstrated that education increases the likelihood of using modern family planning methods. A study in the Northwest and Northeast Nigeria reported a statistically significant association between education and use of modern family planning methods [11]. In Bangladesh it was also reported that education increases the use of modern family planning methods [12]. Similarly in Nepal, the practice of modern family planning methods was higher among the educated [13]. In Namibia the educated women studied were 3 times more likely to use modern family planning methods than those who had no formal education [14]. Ainsworth M et al demonstrated that schooling has a positive relationship with use of modern family planning in 14 Sub-Saharan countries using even after controlling for many other variables [15]. An educated woman is more likely to be aware of the availability of contraceptives. She is also more likely to understand how contraceptives work, believe in their efficacy, hence more likely to use modern contraceptives.

It is important to note that the other three (3) predictor variables (age, residence and marital status) that were tested using binomial logistic regression to determine their effect or otherwise on the use of modern family planning by the women had no statistically significant effect.

In conclusion, we have demonstrated that education is a major factor that affects the use of modern family planning methods among women of reproductive age in the South-eastern geo-political zone of Nigeria. We therefore recommend that female education should be emphasized as an intervention to increase the uptake modern family planning among the women of the South-eastern geo-political zone of Nigeria.
